Introduction

1.1 Context

TrackMe develops health-monitoring devices devoted to measure and record different parameters related to the health status of a person (i.e. body temperature, blood pressure, heart pulse rate and percentage of O_2 in the blood) and also their location. TrackMe health smartwatches are synchronized with an app that gives users access to their data and stats. Also, TrackMe is offering new services to their customers, so as to exploit the data collected from those devices.

1.2 Purpose

This document describes the plans for testing the integration of the created components. The purpose of this document is to test the interfaces between the components as described in Design Document. Every team member who cooperates in the integration tests should read this document.

1.3 Scope

This document represents the Integration Testing Plan Document for TrackMe Service.

Integration testing is a key activity to guarantee that all the different subsystems composing Data4Help and AutomatedSOS interoperate consistently with the requirements they are supposed to fulfil and without exhibiting unexpected behaviours. The purpose of this document is to outline, in a clear and comprehensive way, the main aspects concerning the organization of the integration testing activity for all the components that make up the system.

More precisely, the document presents:

- A list of the subsystems and their subcomponents involved in the integration activity that will have to be tested
- The criteria that must be met by the project status before integration testing of the outlined elements may begin

- A description of the integration testing approach and the rationale behind it
- The sequence in which components and subsystems will be integrated
- A description of the planned testing activities for each integration step, including their input data and the expected output
- Some performance measures that should be performed on the components to check they are fulfilling the requirements
- A list of all the tools that will have to be employed during the testing activities, together with a description of the operational environment in which the tests will be executed

.

1.4 Definitions, Acronyms, Abbreviations

1.4.1 Definitions

- **Health status**: Collection of the last measured overall physical health parameters of a user or a group of users.
- Running circuit: Path defined by the organizer for the run, using the set of nodes.
- Anonymize: The action of anonymize means that an individual's identity cannot be inferred using the available data.
- Parameter out of its normal range: Meaning that the parameter is under or above a defined threshold.

1.4.2 Acronyms

- DD: Design Document
- RASD: Requirement Analysis and Specification Document
- D4H: Data4Help
- ASOS: AutomatedSOS
- T4R: Track4Run
- GUI: Graphical User Interface

• MVC: Model View Controller is a design pattern used for GUIs

• JMS: Java Message Service

• DSL: Digital Subscriber Line

1.4.3 Abbreviations

• [Rn]: n-requirement.

1.5 Revision history

It is important to keep track of the revisions made to this document:

Table 1.1: Revision history timeline

Integration Strategy

2.1 Entry Criteria

In order for the integration testing to be possible and to produce meaningful results, there are a number of conditions on the progress of the project that have to be met.

First of all, the Requirements Analysis and Specification Document and the Design Document must have been fully written. This is a required step in order to have a complete picture of the interactions between the different components of the system and of the functionalities they offer.

Secondly, the integration process should start only when the estimated percentage of completion of every component with respect to its functionalities is:

- 100% for the Data4HelpWebService component
- At least 90% for the LoginService and RegisterService subsystem
- At least 70% for the SearchManager and RequestService subsystem
- At least 50% for the ASOSService applications

It should be noted that these percentages refer to the status of the project at the beginning of the integration testing phase and they do not represent the minimum completion percentage necessary to consider a component for integration, which must be at least 90%. The choice of having different completion percentages for the different components has been made to reflect their order of integration and to take into account the required time to fully perform integration testing.

2.2 Elements to be integrated

In the following paragraph we're going to provide a list of all the components that need to be integrated together.

As specified in TrackMe Design Document, the system is built upon the interactions of many high-level components, each one implementing a specific set of functionalities. For the sake of modularity, each subsystem is further obtained by the combination of several lower-level components. Because of this software architecture, the integration phase will

involve the integration of components at two different levels of abstraction.

At the lowest level, we'll integrate together those components that depend strongly on one another to offer the higher level functionalities of **Data4HelpWebService**. In our specific case, this involves the integration of the **Login Service and Signup Service**, **Search Management**, **Request Management**, **Subscription and Notification Management** subcomponents in order to obtain the **Data4Help Management System** subsystem.

For what concerns the building of the **AutomatedSOS** and **Track4Run** subsystems, the integration activity is actually quite limited; in fact, they simply represent a collection of functionalities belonging to the same area which however are not dependent on one another. As a result of this, their subcomponents don't really interact with each other, and the integration phase will be limited to the task of ensuring that the set of functionalities of each subcomponent is properly exposed by the subsystem. The components involved in this phase are:

- The Data Handler, Health Care Connector and DB Manger subcomponents in order to obtain the AutomatedSOS subsystem.
- The Login, Signup, User, Event, Notification, Data handler, Request and Authentication manager subcomponents in order to obtain the Track4Run Management subsystem.

Some of these subcomponents also directly rely on higher level, atomic components: that is the case, for instance, of the dependency on the **Data Handler component**. These dependencies will be taken care of in the integration process.

Finally, we will proceed with the integration of the higher level subsystems. In particular, the integration activity will involve:

- The already existing components used to achieve specific functionalities: these are the **Health Care Service**, **DBMS** and **Notification system** components.
- Those components and subsystems specifically developed for TrackMeService, that are:
 - On the server side: the **Data4Help Management System**, **Authentication** system, **Search subsystems**, together with the **Data Handler** component.
 - On the client side: the Data4Help Web Application and Track4Run
 Web Application components.

2.3 Integration testing strategy

The approach we're going to use to perform integration testing is based on a mixture of the bottom-up and critical-module-first integration strategies.

Using the bottom-up approach, we will start integrating together those components that do not depend on other components to function, or that only depend on already developed components. This strategy brings a number of important advantages. First, it allows us to perform integration tests on "real" components that are almost fully developed and thus obtain more precise indications about how the system may react and fail in real world usage with respect to a top-down approach. Secondly, working bottom-up enables us to more closely follow the development process, which in our case is also proceeding using the bottom-up approach; by doing this we can start performing integration testing earlier in the development process as soon as the required components have been developed in order to maximize parallelism and efficiency.

Since subsystems are fairly independent from one another, the order in which they're integrated together to obtain the full system follows the critical-module-first approach. This strategy allows us to concentrate our testing efforts on the riskiest components first, that is those that represent the core functionalities of the whole system and whose malfunctioning could pose a very serious threat to the correct implementation of the entire TrackMe infrastructure. By proceeding this way, we are able to discover bugs earlier in the integration progress and take the necessary measures to correct them on time.

It should be noted that **Health Care Service**, **Notification System and DBMS** are commercial components that have already been developed and can thus be immediately used in a bottom-up approach without any explicit dependency.

2.4 Sequence of Component/Function Integration

In this section we're going to describe the order of integration (and integration testing) of the various components and subsystems of TrackMe Service. As a notation, an arrow going from component C1 to component C2 means that C1 is necessary for C2 to function and so it must have already been implemented.

2.4.1 Software Integration Sequence

Following the already mentioned bottom-up approach, we now describe how the various subcomponents are integrated together to create higher level subsystems.

diagrams here......

2.4.2 Subsystem Integration Sequence

In the following diagram we provide a general overview of how the various high-level subsystems are integrated together to create the full TrackMe Service infrastructure.

diagrams here......

Individual Steps and Test Description

In this chapter we'll provide a detailed description of the tests to be performed on each pair of components that have to be integrated. Each pair of components is described in a specific subsection, identified by the <caller; called > notation, containing the list of methods that the <caller > component invokes on the <called > component. For each method we're going to provide a brief description of the input values and the corresponding expected effects on the system.

3.1 Data4Help Management System

3.1.1 Request Management and DBHandler

Insert Request		
Input	Effect	
A NULL parameter	A NullArgumentException is raised.	
A request with an id already	An InvalidArgumentValueException is raised.	
existent in the database		
Formally valid arguments	An entry containing the request data is inserted	
	into the database.	

Delete Request

Input	Effect
A NULL parameter	A NullArgumentException is raised.
A request with an in-existent id	An InvalidArgumentValueException is raised.
Formally valid arguments	The entry containing the request data is deleted
	from the database.

Table 3.1: Request Management parameters

3.1.2 Search Management and DBHandler

Sul	$\operatorname{oscribe}/\operatorname{Get}$	Data

Input	Effect	
A NULL parameter	A NullArgumentException is raised.	
A search with an id in-existent in	An InvalidArgumentValueException is raised.	
the database		
Formally valid arguments	The list of all valid data based on the search id.	

Unsubscribe Data

Input	Effect
A NULL parameter	A NullArgumentException is raised.
A search with an in-existent id	An InvalidArgumentValueException is raised.
Formally valid arguments	The entry containing the search data is deleted
	from the requester's view.

Table 3.2: Search Management parameters

3.1.3 Accept/Reject Management and DBHandler

Update Request Queue (userid, requestid)

Input	Effect
A NULL parameter	A NullArgumentException is raised.
A non-existing RequestID	An InvalidArgumentValueException is raised.
A set of valid parameters to	The new user of the Data4Help is added to
accept	ThirdParty's view in the database.
A set of valid parameters to reject	The new user of the Data4Help is removed from
	request queue in the database.

Table 3.3: Accept/Reject Management parameters

3.1.4 Login Management and DBHandler

Login (userid, tokenid)		
Input	Effect	
A NULL parameter	A NullArgumentException is raised.	
A non-existing user	An InvalidArgumentValueException is raised.	
An empty password	An InvalidArgumentValueException is raised.	
A valid user and password	Returns an InvalidCredentialError.	
combination, which however is		
not the correct one		
A correct and valid user and	Returns a session cookie.	
password combination		

Table 3.4: Login Management parameters

3.1.5 Signup Management and DBHandler

Signup (userid, tokenid)			
Input	Effect		
A NULL parameter	A NullArgumentException is raised.		
An empty parameter	An InvalidArgumentValueException is raised.		
All valid user data in all fields,	Returns an InvalidCredentialError.		
which however belongs to existing			
user			
A correct and all valid user fields	Returns a session cookie and data inserted into the		
	database.		

 ${\bf Table~3.5:~Signup~Management~parameters}$

3.1.6 Check Token (Password Retrieval) and DBHandler

CheckToken (1	userid,	tokenid)
---------------	---------	----------

Checki	onen (aberra, tonema)
Input	Effect
A NULL parameter	A NullArgumentException is raised.
A valid user and secret-Code	Returns False.
combination, which however is	
not the correct one	
A correct and valid user and	Returns True.
secretCode combination	

UpdateUserPassword (userid, tokenid, newPassword)

Input	Effect
A NULL parameter	A NullArgumentException is raised.
A valid user and secret-Code	An InvalidSecurityLevelException is raised.
combination, which however is	
not the correct one	
A correct and valid user and	An InvalidArgumentFormatException is raised.
secretCode combination, but an	
incorrectly formatted password	
A correct and valid user and	Updates the user password in the database.
secretCode combination, and a	
correctly formatted password

3.3 Integration between subsystems

3.3.1 Data4Help system, AutomatedSOS system

EmergencyAlarm (userid, vitalSigns, ContactDetails)				
Input	Effect			
A NULL parameter	A NullArgumentException is raised.			
A userId not correctly formatted	An InvalidArgumentFormatException is raised.			
A userDetails whose contact	An InvalidContactException is raised.			
details are invalid				
Vital Signs out of range	An AlarmRequest is raised and contact is sent to			
	HealthCareService (external component) within 5			
	seconds.			
Vital Signs in range	Overwrite the old data with the latest update until			
	the next data fetch.			

Table 3.8: Data4Help, ASOS integration Management parameters

Performance Analysis

While a full fledged performance analysis of the entire TrackMe infrastructure will be executed only in the system integration phase, it is still useful to perform some preliminary measures on components whose performances can be tested in isolation.

In particular, it is appropriate to verify that the applications for all the target web browser platforms, regardless whether they're destined to users or to third party customers, have reasonable CPU and main memory usages.

As specified in the RASD, the performance requirements of the web applications are the followings:

- The system is provided to serve all the TrackMe wearable device users at the same time simultaneously.
- Technical support for installation is not required, as it is only a web application and users can access it from anywhere where the internet service is provided.
- Under ASOS service, the system makes sure the system responds and notifies the health-care system within 5 seconds, when the thresholds are below the certain defined level.
- Users will rely on the application in order to organize their send or accept/reject requests for data and notifications, so we have to guarantee quick, reactive and correct response.

Furthermore, using the load testing tools will ensure the application performance in peak traffic and under extreme stress conditions. However, this number should be reconsidered during the development phase taking into account the improvements in the browsers and add-ons and responsive technology that may occur meanwhile.

These tests will be performed using the appropriate performance analysis tool provided with the SDK of each web platform.

Tools and Testing equipment

5.1 Tools

In order to test the various components of TrackMe more effectively, we are going to make usage of a number of automated testing tools.

For what concerns the business logic components running in the Java Enterprise Edition runtime environment, we are going to take advantage of two tools.

The fi

rst one is the Arquillian integration testing framework. This tool enables us to execute tests against a Java container in order to check that the interaction between a component and its surrounding execution environment is happening correctly (as far as the Java application server is involved). Specifically, we are going to use Arquillian to verify that the right components are injected when dependency injection is specified, that the connections with the database are properly managed and similar container-level tests.

The second tool is the **JUnit framework**. Though this tool is primarily devoted to unit testing activities, it's still a valid instrument to verify that the interactions between components are producing the expected results. In particular, we are going to use it in order to verify that the correct objects are returned after a method invocation, that appropriate exceptions are raised when invalid parameters are passed to a method and other issues that may arise when components interact with each other.

Furthermore, as we have already mentioned briefly in the previous chapter of this document, we are going to use specific performance analysis tools to make sure that the applications for all the target mobile platforms, regardless whether they're destined to individual users or to third party users, have responsive web application and quick responses in peak traffic also. Depending on the specific platform we are targeting, the tools we are going to use are:

- Apache JMeter: It is a Java platform application. It is mainly considered as a performance testing tool and it can also be integrated with the test plan.
 - System Requirements: It works under Unix and Windows OS
 - Open source

- LoadUI: LoadUI lets you create and update test cases while you run them.
 - System Requirements: It works under MacOS, Unix and Windows OS
 - Open source

Finally, it should be noted that despite the usage of automated testing tools, some of the planned testing activities will also require a significant amount of manual operations, especially to devise the appropriate set of testing data.

5.2 Test Equipment

All the integration testing activities have to be performed within a specific testing environment.

Since TrackMe Service incorporates both a set of client components and a back-end infrastructure, we must define the characteristics of the devices that have to be used in each of these two areas.

For what concerns the browser side of the testing environment, the following devices are required:

- For web browser, computer need:
 - Windows (chrome, IE, edge): Windows 7, Windows 8, Windows 8.1, Windows 10 or later
 - MacOS: Mac OS X 10.6 through Mac OS X 10.11 or higher
 - An Intel Pentium 4 processor or later that's SSE2 capable
- Internet Connection Broadband (high-speed) Internet connection with a speed of 4 Mbps or higher.

These devices will be used to test the browser versions of the web applications. It should be noted that these are general guidelines to drive the selection of the testing devices in a way that covers the widest range of possible configurations. Some display sizes or resolutions may not be offered by all product families.

As a general note, we should consider the possibility of performing an analysis of the browser market to identify the most common display sizes and resolutions right before starting the integration testing phase, in order to better reflect the typical usage scenarios we will encounter in the real operating environment.

As for the back-end testing, the business logic components should be deployed on a cloud infrastructure that closely mimics the one that will be used in the operating environment. Specifically, the testing cloud infrastructure needs to run the same operating system, the same Java Enterprise Application Server, the same Health Care Service System and Notification Service (Alarm interface) middle ware (message brokers) and the same DBMS. As such, it is strongly suggested to use a scaled down version of the final operating cloud infrastructure chosen from the same service provider.

Depending on the actual implementation decisions, the specific software components may change.

Required Program Stubs and Test Data

6.1 Program Stubs and Drivers

As we have mentioned in the Integration Testing Strategy section of this document, we are going to adopt a bottom-up approach to component integration and testing.

Because of this choice, we are going to need a number of drivers to actually perform the necessary method invocations on the components to be tested; this will be mainly accomplished in conjunction with the JUnit framework.

Here follows a list of all the drivers that will be developed as part of the integration testing phase, together with their specific role:

- Data Access Driver: this testing module will invoke the methods exposed by the DB Handler component in order to test its interaction with the DB Manager.
- Request Management Driver: this testing module will invoke the methods exposed by the Request Management subcomponent, including those with package level visibility, in order to test its interaction with the DB Handler, Notification System and the Subscription Management components.
- Search Management Driver: this testing module will invoke the methods exposed by the Subscription Management subcomponent in order to test its interaction with the DB Handler, Notification System and the Request Management components.
- Login Management Driver: this testing module will invoke the methods exposed by the Login Management subcomponent in order to test its interaction with the DB Handler and the token System components.
- Health Care Connector Driver: this testing module will invoke the methods exposed by the Health Care Connector Management subcomponent in order

to test its interaction with the DB Handler and the Health Care Service - external System components.

- Notification Management Driver: this testing module will invoke the methods exposed by the Notification Management subcomponent in order to test its interaction with the DB Handler, Request system and Search system components.
- Subscription Management Driver: this testing module will invoke the methods exposed by the Subscription Management subcomponent in order to test its interaction with the DB Handler and Search system components.
- Account Management Driver: this testing module will invoke the methods exposed by the Check Token Management subcomponent in order to test its interaction with the DB Handler, Login system and Signup system components.

While the bottom-up approach in general doesn't require the usage of any stubs as the system is developed from the ground up, a full test of the core system isn't possible without introducing a few of them. In fact, there is a mutual dependency between the clients (which send requests) and the core system (which replies to them). Since we are developing and integrating the system from the core, we are going to introduce stubs to simulate the presence of clients until they are fully developed. In practice, the only purpose of these stubs is to write on a log that they have correctly received the messages.

6.2 Test Data

In order to be able to perform the record of tests that we have specified, we are going to need:

- A list of both valid and invalid individual or third party users to test the Signup Management component. The set should contain instances exhibiting the following problems:
 - Null object
 - Null fields
 - Invalid data in one or more fields
 - Tax certificate not compliant with the legal format
 - Valid data in all fields
- A list of both valid and invalid individual or third party users to test the Login Management component. The set should contain instances exhibiting the following problems:

- Null object
- Null fields
- Invalid data in one or more fields
- valid data but system down
- Valid data in all fields
- A list of both valid and invalid requests to test the **Request Management** component. The set should contain instances exhibiting the following problems:
 - Null object
 - Null fields
 - Invalid data in one or more fields
 - valid data but incorrect format
 - Valid data in all fields
- A list of both valid and invalid searches to test the **Search Management** component. The set should contain instances exhibiting the following problems:
 - Null object
 - Null fields
 - Invalid data in search
 - valid data but does not exist in DB
 - Valid data
- A list of both valid and invalid searches to test the **Subscription Management** component. The set should contain instances exhibiting the following problems:
 - Null object
 - Null fields
 - valid data but does not exist in DB
 - Valid data
- A list of both valid and invalid notifications to test the **Notification Management** component. The set should contain instances exhibiting the following problems:
 - Null object
 - Null fields

- valid data but does not exist in DB
- Valid data
- A list of both valid and invalid notifications to test the Health Care Service Management component. The set should contain instances exhibiting the following problems:
 - Null object
 - Inconsistent data against threshold
 - Consistent data against threshold
 - Valid data

More specific information about the required test data can be found by analysing the inputs of all the test cases described in chapter 3.

6.3 Test Scenario

Scenario testing is a software testing activity that uses scenarios: hypothetical stories to help the tester work through a complex problem or test system. The ideal scenario test is a credible, complex, compelling or motivating story the outcome of which is easy to evaluate. The following high-level set of scenarios were considered for **Data4Help** system:

Scenario List (Data4Help Module)

SC01	Validate the login functionality of the system
SC02	Validate the login functionality of the system with blank data
SC03	Validate the Register functionality of the system
SC04	Validate the Register functionality of the system with blank data
SC05	Validate if third party is able to request individual's data
SC06	Validate if third party is able to request bulk data
SC07	Validate the individual's response to request (Accept/Reject)
SC08	Validate third party is able to search for the subscribed data on its dashboard
SC09	Validate Individual is able to view for the subscribers data on its dashboard

Table 6.1: Test Scenario List

6.4 Test Cases

A test case is a specification of the inputs, execution conditions, testing procedure, and expected results that define a single test to be executed to achieve a particular software testing objective. We will define a number of test cases against the test scenarios above stated to cover the Data4Help complete system. The following test cases are considered against the test scenarios:

• Login Positive Test Case

Test Scenario ID	Login-1	Test Case ID	Login-1A
Test Case Description	Login-Positive	Test Priority	High
Pre-Requisite	A valid user account	Post-Requisite	NA

Test Execution Steps:

S. No.	Action	Input	Expected Output	Actual Output	Test Result
